

FOLFOX is a **combination chemotherapy regimen** primarily used for treating colorectal cancer, though it is also used for other gastrointestinal cancers such as pancreatic, stomach, esophageal, and biliary tract cancers<sup>[1236](#)</sup>. FOLFOX combines three drugs:

- **FOL**inic acid (leucovorin)
- Fluorouracil (5-FU)
- **OX**aliplatin<sup>[136](#)</sup>

These medications work together to disrupt the formation and function of DNA in rapidly dividing cells, thus targeting cancer<sup>[125](#)</sup>.

The **treatment regimen** typically involves 12 cycles, each lasting 14 days (2 weeks) and spanning about 6 months in total<sup>[246](#)</sup>. During each cycle:

- Oxaliplatin and folinic acid are administered intravenously over 2 hours (days 1 and 2)<sup>[2346](#)</sup>.
- Fluorouracil is given as both a short injection and a prolonged infusion over 22–46 hours via a portable pump, which patients often take home and return after about two days for disconnection<sup>[2346](#)</sup>.

There are multiple variations of FOLFOX (e.g., FOLFOX-4, FOLFOX-6), differing in dosing and timing<sup>[156](#)</sup>.

**Efficacy:** Studies have shown that FOLFOX improves overall survival when used after surgery for stage 3 colorectal cancer, with a 5-year survival rate reported at about 77.9% in a key study, and no major efficacy difference compared to FOLFIRI for stage 4 disease<sup>[39](#)</sup>.

**Side effects** commonly include:

- Fatigue
- Nausea and vomiting
- Mouth sores
- Low blood counts (risk of infection, anemia, or bleeding)
- Sensory neuropathy (numbness, tingling with cold sensation), mainly due to oxaliplatin<sup>[510](#)</sup>.

FOLFOX may be adjusted to minimize side effects<sup>310</sup>.

FOLFOX is generally administered as an outpatient regimen, and is considered standard of care for many people with colon cancer, especially in adjuvant (after surgery) and advanced (metastatic) settings<sup>16</sup>.
